Notes on the AI suggestions

Mailles Machiana / COMP3415 A2

AI assistance was used for tests, implementation and writing after Checkpoint A. The shared-builder suggestion came up during implementation; the other options were considered when writing this evaluation.

Sharing the calculations - useful

Quote and place had almost the same code. `_build_quote` removes that repetition and uses the state already loaded by the caller. The refactor kept the same failures before the bugs were fixed. Tests also compare quote and order prices.

Dictionary lookup - useful in some places

It works for stock changes with validated IDs. Raw IDs are different: a list or dictionary can cause TypeError, when the service should raise ValueError. Keeping the small validation scan was fine for five products. This wasn't a measured speed improvement.

round() for the discount - doesn't fit the rule

Python rounds ties to even. The spec wants half cents rounded up, so the integer formula stayed. A 5005-cent fixture needs a 501-cent discount and checks that case.

Reusing free delivery for express - wrong result

CR-01 says express always costs $12. Reusing standard delivery's threshold would waive it on bigger orders. A separate branch keeps the rule clear. Tests check that the fee isn't waived or discounted.

Bigger changes - not needed here

A database and delivery classes would add work without solving another required problem. JSON and a short conditional were enough. Duplicate lines stay separate; only the stock check adds their quantities together.

The 49 passing tests and seven caught wrong changes support these decisions. They don't mean there can't be another bug.
